

AI Workflow Builder

An AI-powered visual workflow builder that lets users automate complex tasks by describing them in natural language. Instead of manually creating workflows, users simply state their goal, and an AI planner generates a complete workflow composed of specialized agent nodes (such as Research, Analysis, Writer, Critic, or Custom Agents). Users can inspect, modify, and extend the generated workflow through an interactive drag-and-drop canvas before executing it.

Each node acts as an independent AI agent with a specific responsibility, passing structured outputs to downstream nodes. During execution, users can watch the workflow progress in real time, inspect each agent's reasoning and outputs, retry failed steps, or edit individual nodes without rebuilding the entire workflow.

The project combines modern React frontend architecture with agentic AI concepts, showcasing visual workflow editing, real-time execution, state management, and multi-agent orchestration in a developer-friendly interface. It bridges the gap between no-code automation tools and AI assistants by making autonomous agent workflows transparent, editable, and interactive.
